

# Cryptographic Protocols

## Solution to Exercise 6

### 6.1 Permuted Truth Tables

- a) Peggy chooses a random permuted truth table for the  $\wedge$ -function and commits to its elements. Vic chooses a random challenge bit  $c$  and sends it to Peggy. If  $c = 0$ , then Peggy opens the whole table and Vic checks if it is a permuted  $\wedge$ -table. If  $c = 1$ , Peggy takes the blobs  $(d_1, d_2, d_3)$  from the row corresponding to the triple  $(b_1, b_2, b_3)$  and proves (using the ZK protocol for equality) that  $\forall i \in \{1, 2, 3\}$   $d_i$  and  $c_i$  are commitments of the same value.

Note that the commitments used in the above construction are of type B (i.e., perfectly binding). We show that the above protocol is a zero-knowledge proof of the statement “the committed values  $(b_1, b_2, b_3)$  corresponding to the commitments  $(c_1, c_2, c_3)$  satisfy the relation  $b_1 \wedge b_2 = b_3$ .”

COMPLETENESS: Follows immediately from the completeness of the protocol for blob equality.

SOUNDNESS: Assume that  $b_1 \wedge b_2 \neq b_3$ . If Peggy commits to a valid permuted truth table in the first step, Peggy cannot answer the challenge  $c = 1$  as there is no row in this table with commitments corresponding to  $b_1, b_2, b_3$ . If Peggy commits to an invalid table, then she cannot answer the challenge  $c = 0$ , as the commitment is binding. Hence, the cheating probability of Peggy for each round is approximately  $1/2$  (the “approximately” stems from the fact that, in case  $c = 1$ , Peggy might still be able, with some small probability, to cheat in the equality proof).

ZERO-KNOWLEDGE: We prove the (computational) zero-knowledge property only informally. We need to show that there exists an efficient simulation  $S$  producing a transcript which is (computationally) indistinguishable from the transcript resulting from a real protocol execution between the prover  $P$  and (a possibly dishonest) verifier  $V'$ .

The simulator  $S$  can produce a transcript as follows: First,  $S$  computes a valid permuted truth table and commits to it. If  $V'$  sends the challenge  $c = 0$ , the simulator opens the committed table. If  $V'$  sends  $c = 1$ ,  $S$  uses the simulator  $S'$  for the blob equality protocol to compute a transcript of a proof of equality for  $c_i = d_i$  ( $i = 1 \dots 3$ ), where the  $d_i$ 's are commitments corresponding to a randomly chosen row of the permuted truth table. Note that, by the computational hiding property of the commitments, the transcript produced by  $S'$  is computationally indistinguishable from the real interaction even if the  $d_i$ 's are commitments to different values than those in the  $c_i$ 's.

- b) If Peggy knows the input to the circuit, then she can compute (by evaluating the circuit in a gate-by-gate manner) the bits on the wires. She commits to all those bits and sends the blobs to Vic. Subsequently, she uses the protocol from a) for each

gate ( $\neg$ -gates are treated similarly to  $\wedge$ -gates) to prove that the committed values are consistent with the circuit. To convince Vic that the output of the circuit is in fact 1, Peggy and Vic use a fixed commitment of 1, i.e., a commitment that is hard-coded into the protocol.

- c) In the BCC protocol from the lecture, when processing the circuit, Peggy blinds every wire using a random bit. In the protocol from **b**), this is not necessary, but we need the additional zero-knowledge proofs of equality of committed values.

## 6.2 Protocols and Specifications

- a) Protocol 1 does not satisfy Specification 1, since in the protocol  $P_2$  outputs  $x_1 \wedge x_2$  and in the specification  $P_2$  outputs  $x_1$ , which is different than  $x_1 \wedge x_2$  in the case where  $x_1 = 1$  and  $x_2 = 0$ .

Protocol 1 satisfies Specification 2, since the parties output the same in the protocol and in the specification.

- b)  $P_2$  is semi-honest: Protocol 1 is not secure if  $P_2$  is passively corrupted. We need to argue that there is an adversary in Protocol 1 that achieves something, such that no adversary in the specification achieves the same.

We can see that in Protocol 1  $P_2$  learns the message  $x_1$ , which cannot always be computed from the input and output of  $P_2$ . Consider an adversary in Protocol 1 who chooses the input  $x_1$  of party  $P_1$  uniformly at random. Furthermore, consider the case where  $x_2 = 0$ . Then,  $x_1 \wedge x_2 = 0$ , and the adversary in the specification has to guess  $x_1$ , in which it succeeds with probability at most  $\frac{1}{2}$ .

$P_2$  is malicious: The protocol is secure in the case where  $P_2$  is actively corrupted. We argue that anything an adversary can do in Protocol 1, there is another adversary in the specification that achieves the same.

In the protocol execution, the adversary obtains the input  $x_1$  of  $P_1$ , and then can output an arbitrary value from  $x_1$  and  $x_2$ .

In the specification,  $P_1$  sends  $x_1$  to the trusted party. Here, the adversary corrupting  $P_2$  sends 1 to the trusted party. Then, it receives  $x_1 \wedge 1 = x_1$ , and outputs the same as what the adversary in Protocol 1 outputs.

- c) *Two passive corruptions*: If  $P_1$  and  $P_2$  are passively corrupted, the adversary in the specification knows  $x_1$ ,  $x_2$  and  $x_1 \wedge x_2 \wedge x_3$ . Hence, it can generate all messages that an adversary in Protocol 3 see (which consists of the messages  $x_1$ ,  $x_1 \wedge x_2$  and  $x_1 \wedge x_2 \wedge x_3$ ). However, when  $P_1$  and  $P_3$  are passively corrupted, the adversary in the specification (who knows  $x_1$ ,  $x_3$  and  $x_1 \wedge x_2 \wedge x_3$ ) cannot compute  $x_1 \wedge x_2$ .

If the adversary in Protocol 2 corrupts all players, the adversary in the specification can generate all messages of the protocol, and hence the protocol is secure.

*Two active corruptions*: If  $P_1$  and  $P_2$  are actively corrupted, the adversary in the specification knows  $x_1$ ,  $x_2$  and  $x_1 \wedge x_2 \wedge x_3$ . Hence, it can generate any message that an adversary sees in Protocol 3.

In the case where  $P_1$  and  $P_3$  are corrupted, the adversary in the specification can input 1 to the trusted party on behalf of  $P_2$  and  $P_3$ , to learn the input of  $P_1$ . Hence, it can generate all messages that can be seen by any adversary of Protocol 3 without changing the output ( $P_2$  has no output).
